(1723) TCT mentorship - Lecture 6 | Advanced TCT schematics - YouTube
https://www.youtube.com/watch?v=1RYBUn8AAPY

Transcript:
(00:03) what is up guys and welcome to lecture six of the TCT mentorship where we will be talking about Advanced TCT schematics okay now in the beginning lectures we have laid the foundation of our trading we've talked about Market structure ranges supply and demand liquidity and then in lecture five we went into TCT schematics but because you know the foundation you kind of understand why they work okay and the theory behind them and in lecture five I taught you everything that you need to know on how to identify them what to look for how to
(00:46) trade them how to confirm them the targets the invalidations and all that good stuff okay in this lecture we will be going over the advanced details that will just turn you into a pro a master okay is those little tweaks to improve your risk to reward to potentially extend your targets beyond the opposite range extreme point and all that good stuff however it is important that you understand and master the basics first okay so if you are still having some trouble identifying the proper uh TCT schematics first I would love to see you
(01:30) and your questions in the Discord server okay it's a community of likeminded Traders where I myself will also be located to answer any questions that you may have about the course or live price action and furthermore you'll get exclusive trading setups you'll basically just be trading with me and all of the TCT Traders okay so I hope I will see you in there but um if not that is totally fine just make sure that you put your ego aside and realize hey am I ready to go into the advanced section because if you're not and you'll still
(02:16) go into this Advanced section you will be putting your focus in the wrong place because you need to master the foundation first before you go into any advanced details because the advanced details will not matter if you don't understand the basics okay so let's just hop straight into it because I think this will be a longer lecture taking a sip of my water okay so the first Advanced concept I want to talk about are distributions that can turn into accumulations and vice versa so when we are trading TCT schematics we
(03:03) always Target the opposite range extreme point and based on the bigger picture the context we can determine you know if we it will have follow through or not and I've have been telling you guys this for a reason why well the same way if price starts deviating the low confirming a potential TCT accumulation schematic the same way price could be confirming a TCT distribution once that range highight Target of the accumulation gets hit but starts to deviate so let me um visualize it for you guys so let's say we are trending up
(03:51) okay let's say we are trending up and we have a model 2 distribution right here we pull our range there we go range high range low deviation this meets all the requirements for a valid third tap and then we go down okay now what happens or what can happen is that price starts coming down but instead of breaking the low okay instead of breaking the low we will start deviating the low well if that happens we could have a potential accumulation schematic in the making where this model 2 distribution with this one it's two and it's three

(04:40) can turn into a model 2 accumulation and that's always a possibility and that's why I'm normally always referring to the Target being the opposite range extreme point because a distribut can always go over into an accumulation just like the accumulation can go over into a distribution okay and this is why building context and understanding where we are at on the chart is crucial for correct expectations regarding if your accumulation for example will have follow through or turned into a distribution okay so let's look at it

(05:29) from a live live trading example so right here we have BTC and it's the 25th of July it's the 25th of July and let's build some context okay let's build some context so as we can see right here we had our range low our range low got deviated and we broke structure back inside the range lower highs and lower lows right here we broke it back to bullish expectational order flow changes to higher low and higher high and right here we entered into this one or this 8 Hour order block for a potential higher low for a higher high now how do we

(06:14) confirm a higher low for a higher high by looking at that structure from top to bottom and when that breaks back to bullish that is when we can have that confirmation using the domino effect to have a rotation back up towards that high okay so that is the c context that is the thing you need to be aware of when zooming in on the lower time frame cuz right here we can see on the lower time frame we entered that POI and we broke our structure back to bullish right here okay Mark structure break back to bullish after a mark break back to

(06:53) bullish but followed a higher low for a higher high in an uptrend we pull our range from top to bottom and there we go okay there we go so zooming in on what we got going on right here is we have our Range High we have our range low and we have deviation one not closing above our dl2 so it's a valid second tab so we're going to extend it towards that high right there and then we have a potential tab three that swept all liquidity okay this did not go higher on other exchanges I'm on the usdt buy bit right now it didn't go

(07:34) higher here as well it looks like it it looks like equal Highs but it did not so it meets the requirements of sweeping all that extreme liquidity now we just need to wait for a structure confirmation okay structure confirmation we wait for that break of structure low right here it was two consecutive candles on any other exchange and then whenever that break of sh appears right there that is when we can go short okay that is when we can go short now it is important okay to recognize now is this distribution going to have

(08:14) any follow through or will accumulation make more sense I just gave you the bigger context about this breaking back to bullish being in a bigger uptrend and potentially you know having having that rotation all the way back up towards that high right here okay using the domino effect so I would not be aiming for this distribution to have any th follow through matter of fact I'm expecting it to turn into an accumulation okay so what developed from here is that price are deviating the low coming back up and from here we turned it into an

(08:59) accumulat schematic so as we can see right here we had that deviation staying inside of our dl2 mitigating some Demand on the left we can see the top of this structure Demand with that inefficiency getting mitigated and then price coming back for some sort of extreme Demand right here this last little order block okay breaking structure back to bullish right there confirming that this is the the third Tab and price can have a rotation back up higher let's make it beautiful there we go now guys for the accumulation right

(09:48) now yes this accumulation can actually have some follow through um referring to the bigger context we just discussed because technically speaking if we start breaking that high we can turn uh or we can take this trade all the way back up towards that high for a fa 14 risk to reward setup okay and that's also exactly what happened if I um play it through eventually that got hit right there it took a while but it did get hit but the beauty of it is the fact that you can see right here that a distribution okay a distribution can

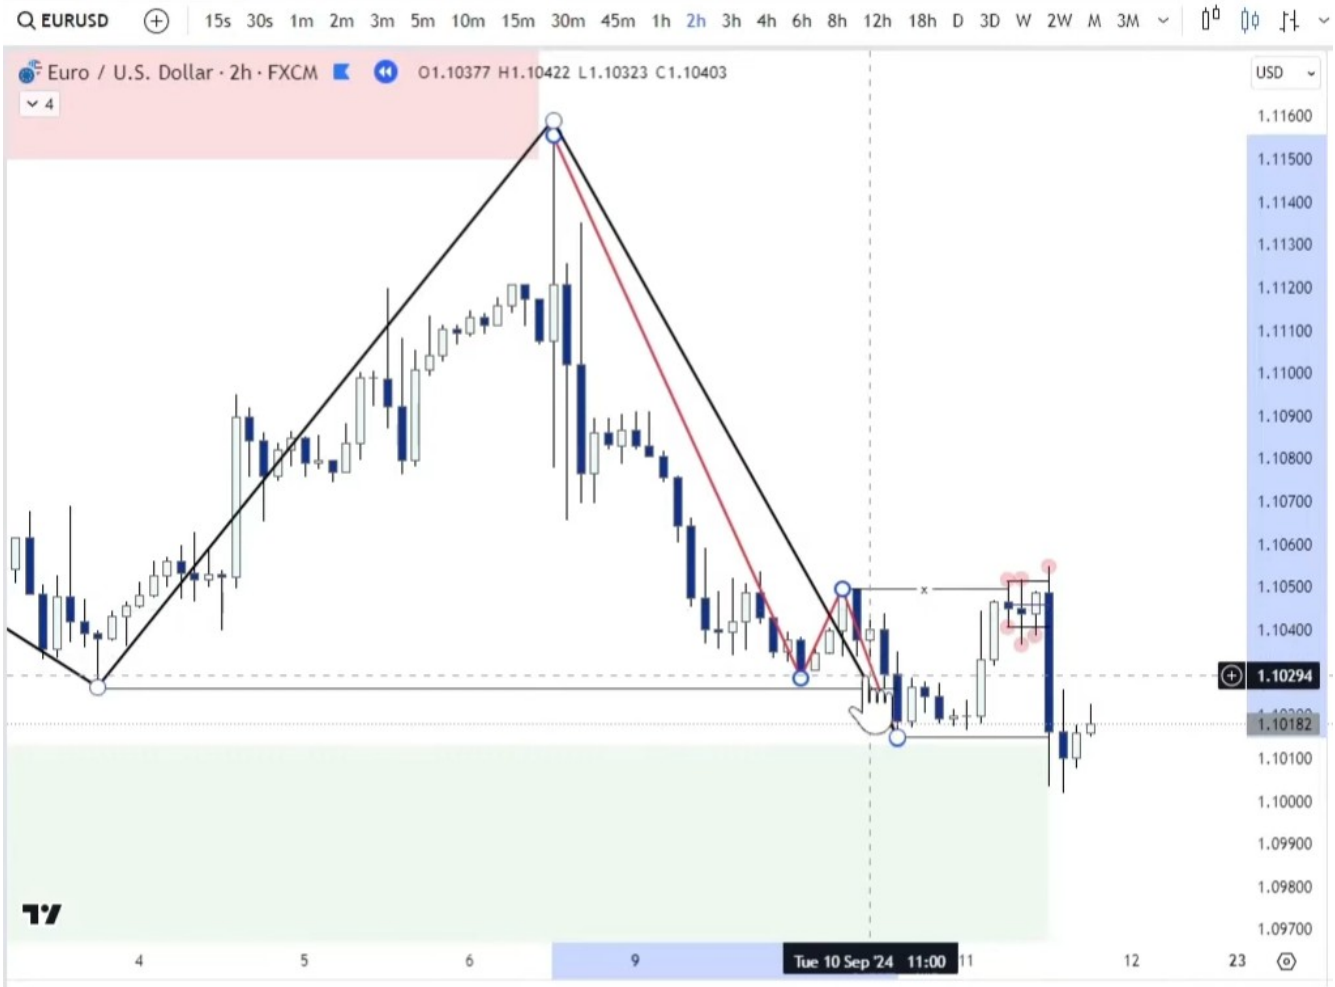
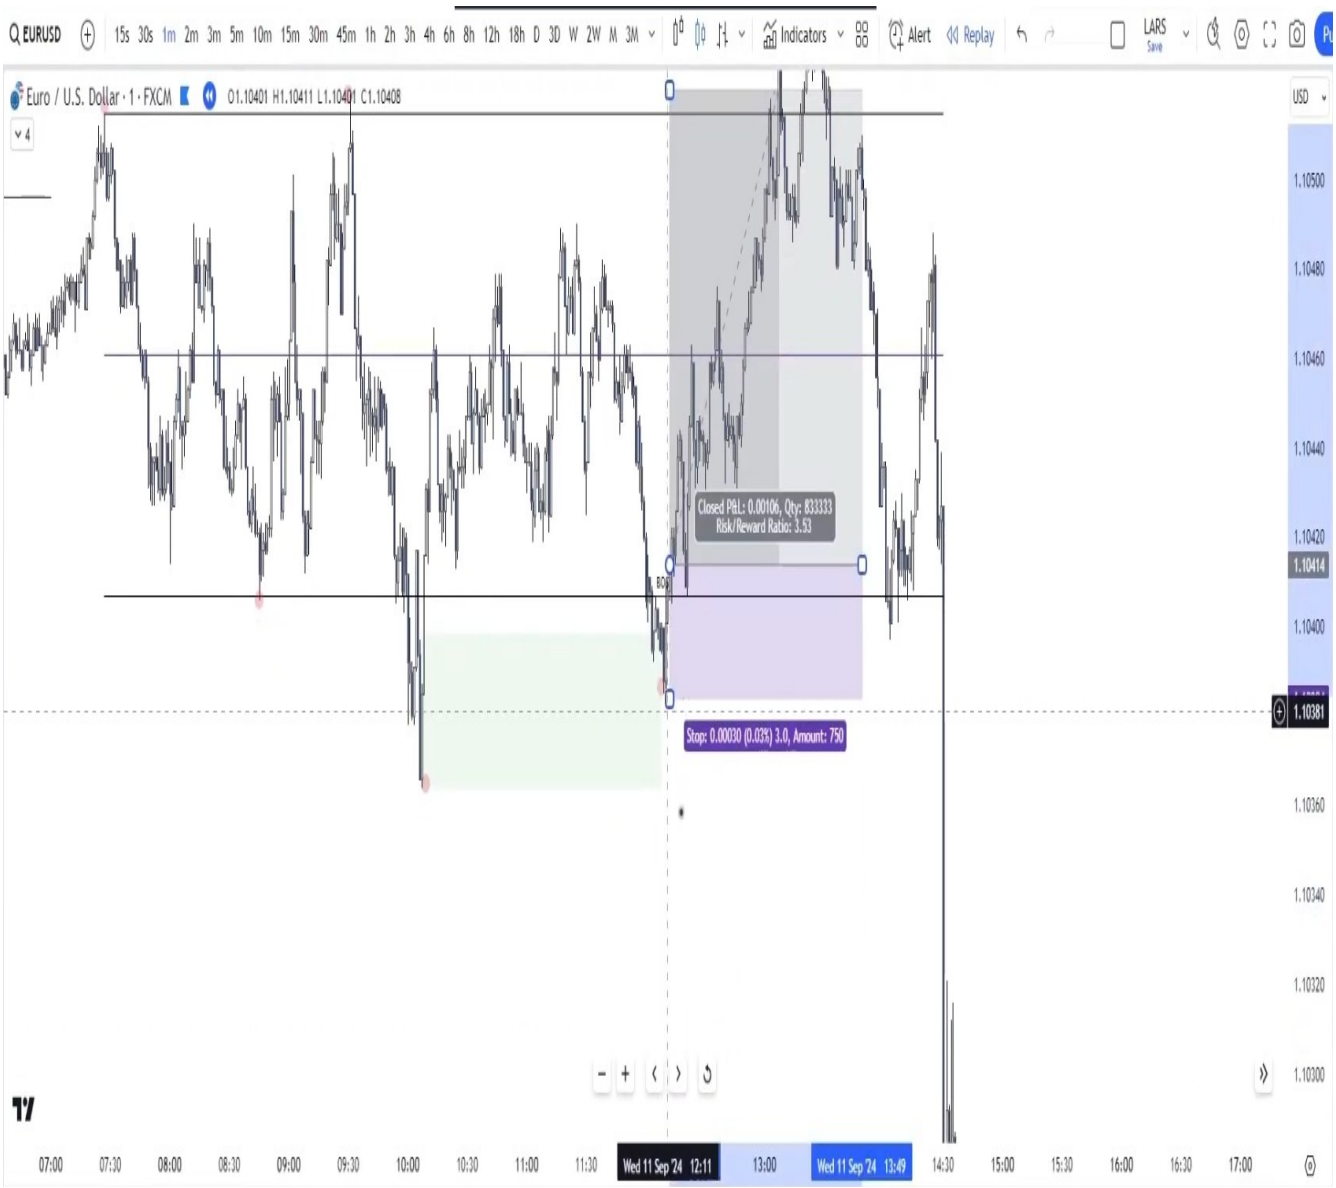
(10:31) turn into an accumulation okay and you will see this all the time all over the place especially when trading lower time frame schematics it happens all the time and that is why understanding structure to lay that Foundation to build that context is so important now another example is right here on Euro okay so if we want to build some context on Euro we were basically downtrending okay we were downtrending in a macro Trend down lower highs and lower lows where this was our most local downtrend of lower high and lower low



(11:22) right here let's make that R so breaking that r high will be your first signs of strength not breaking that rat high is very weak because it's the is the most local downwards Trend okay it's the most local downwards Trend so if you cannot even break your Lo most local market structure high back to bullish that is bearish okay and we started wicking it creating a range well what happened we are trending up okay higher lows and higher highs range high range low deviation at the bottom right here we zoom in on the 2 minute okay we zoom

(12:09) in on the two minute got the deviation high as well okay deviation at the lows deviation at the highs got that two-minute demand zone right here two-minute order block for our extreme demand came into it went on the lower time frame like the one minute confirm the entry and then that is your long now I was expecting a rejection from this liquidity Point based on some unfinished candle business discussed in one of my YouTube videos as well um so I was expecting lower here but as you can see price had that model 2 accumulation



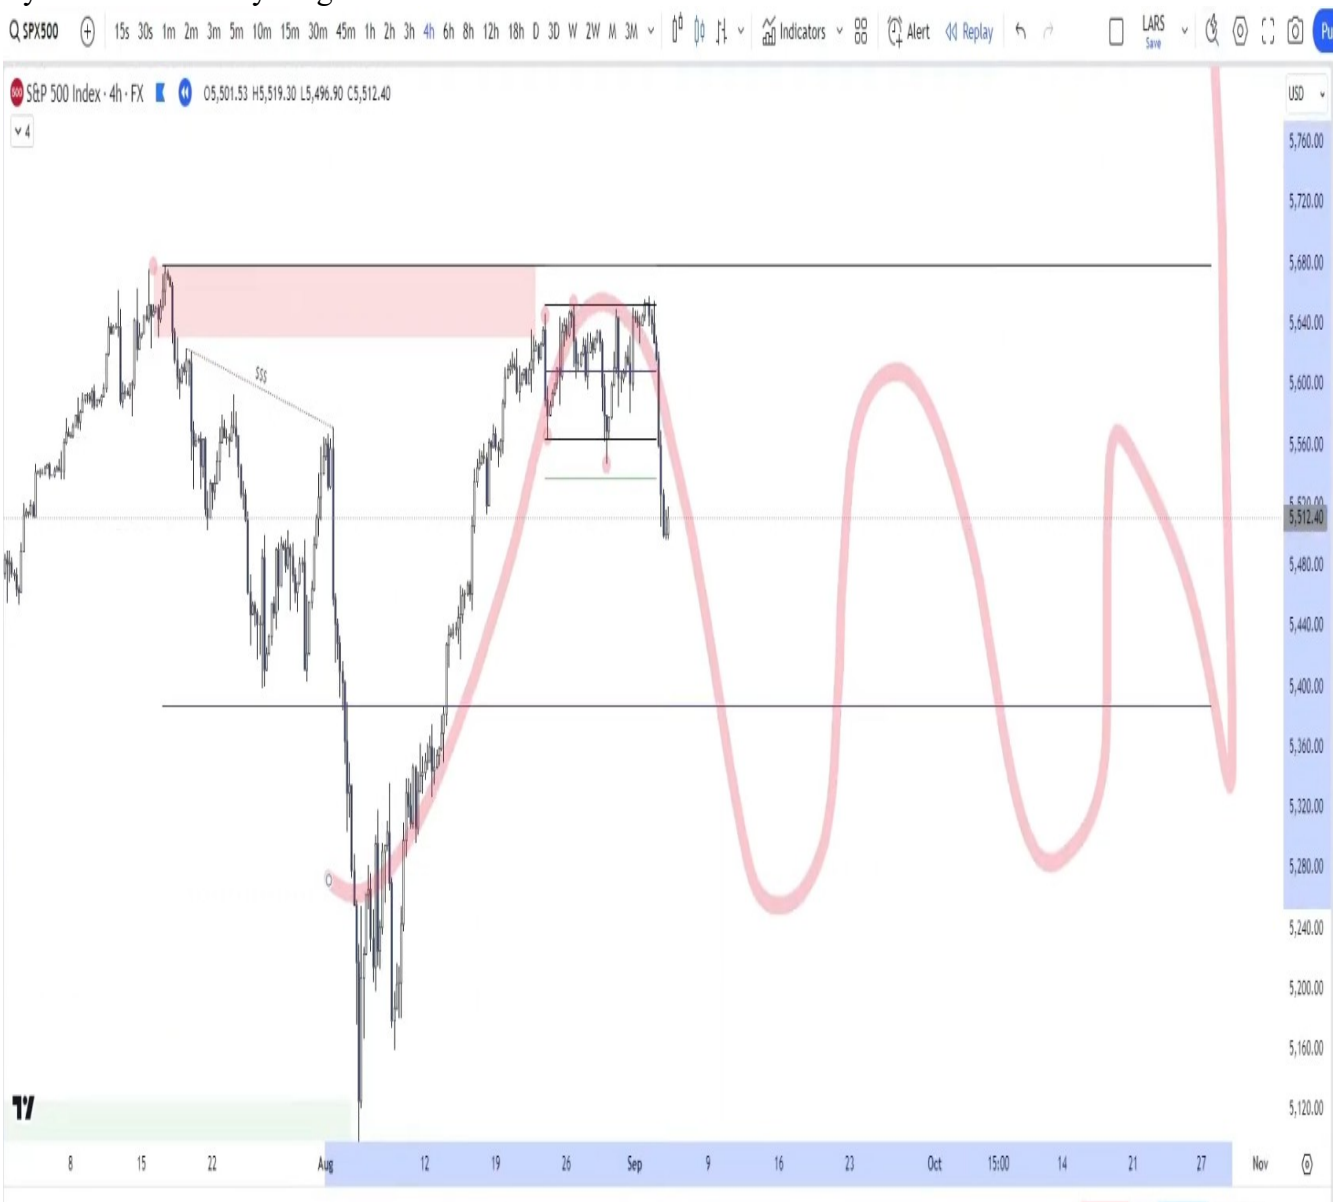
(12:49) that got confirmed right here you could have longed it back up could have longed it back up towards that Range High okay and then from there you can see it turned into that model one distribution where right here we got the break of structure confirmation and then right there you could have shorted back down and that actually had some follow through because we were already expecting price to go lower boom you see how that worked this model two accumulation brought us to the high that turned us into a model one
(13:29) distribution schematic literally guys you see this everywhere now there is a difference between this accumulation flowing over into this distribution and this distribution flowing over into the accumulation why well it happens quite often that prior to confirming either the accumulation or the distribution you have deviations on both sides so prior to confirming the accumulation you already had a deviation of the highs as well you didn't have that here right here when you confirmed that distribution you oh you confirmed
(14:13) that distribution you didn't have the deviation at the lows yet okay and in the situations where you do have deviations on both ends um you can't just Target the opposite range EX Stream Point once

your confirmations have been met because there's always the possibility of price turning into an opposite model 2 schematic okay and we have different examples right here so what I mean if I have to draw it for you guys first is let's say we have that accumulation schematic okay we deviate the high we deviate the low okay and we get that confirmation
(15:00) right here now let's say this is our range and we have our Range High we have our range low right here boom boom deviation one deviation two and right here we confirm like an extreme liquidity sweep making a valid third tap there you go let's say there is Supply let's say there is Supply right at that high in that pivot point of that uh deviation at the highs we are trading the model 2 accumulation right here but we cannot just Target our new deviation High because it has always the possibility to turn into a distribution A1 A2

(15:52) A3 so it's very important you watch that structure from the low up because if that breaks back to bearish that will confirm the distribution right but you always have to be aware of that and do not get trapped into thinking oh we have to come towards that second tap high no it can turn into a distribution so be aware of that that's exactly what happened right here we had some Supply but structure never broke back to bearish okay this right here was a wick so it never broke back to bearish also not on the

higher time
(16:27) frame uh so there there was no reason to panic yet this two-minute Supply zone right here um but structure never broke back to bearish right you had highs higher lows so there was no reason to panic um but if it did break structure coming into that two-minute order block right here that is a sign to go short and to take profit on that accumulation schematic trade okay based on the drawing right here you can see on the right they're basically the same however structure didn't break so then you can just trade the model one if you get the
(17:08) confirmations another great example of this is on the SNP most recently because guys these TCT schematics you can trade on any asset okay stocks Forex Commodities um Futures you name it it works everywhere absolutely everywhere now what we can see right here is that on the 6h hour time frame okay on the 6- hour time frame we can see we have a higher low and a higher High drawing our structure P our range from top to bottom there we go we have our Range High we have a range low we have deviation at the high and we have a deviation at the low

(17:57) indicating a sign of an accumulation and a sign of a distribution okay we don't know in that moment which one it will be we can have an expectation and we can already check what that expectation could be why okay let's check by building bigger context I'm zooming out we are trending up in an uptrend I pull my range from top to bottom okay so we have a range right here price came into premium pricing of that range right in the pivot point of our Market sh shapo we have Supply this is Extreme Supply because it's the last
(18:40) Supply remaining before taking your Range High you're in extreme premium pricing so what do you think makes more sense an accumulation or a distribution obviously it will be a distribution because prices in ranges they rotate you just had a rotation towards the Range High now we can come back down again until price decides to either break up or down but we want to be looking for bigger shorts in the premium section of the range and bigger Longs in the discount section you don't want to try and catch a crazy long in the extreme



(19:13) premium pricing of the range so again that's when building context plays a big part so what we can see right here that we have a deviation at the low and the highs and we had Supply right here we had Supply right there for a potential valid third tap let's check our structure we can see we had a

market structure confirmation right on this break called a break of structure right there on the break of structure you got that confirmation can I Target okay can I Target the range low not per se because this can turn

(19:59) turn into an accumulation schematic because you also already have the deviation at the bottom right here so let's check where is that extreme demand and where is that extreme liquidity right here we see that sixh hour order Block in that pivot point of that deviation just put that there then let's grab our extreme liquidity that will be this low it's the most obvious low it's a structure from top to top to the bottom keep that demand make this extreme liquidity there you go so the moment you take that extreme liquidity

(20:38) here this could be a one this could be a two and this can be a three we just have to wait for a structure confirmation just like with anything else right now right here you got that structure confirmation you got the SFP first and then right after that you you got that break of structure right there so that's the confirmation that this model 2 is confirmed and price will come towards that Range High making this model 2 distribution fail okay so the moment you break structure right here that's your risk on trigger for Longs and your risk

(21:19) off trigger for the short so when you go short we can just Target that uh range low now keeping that bigger context and a bigger picture in mind we are still expecting a distribution but if the distribution model 2 failed to confirm or fail to hit its Target and that failing is confirmed on that bullish break right here we can expect it to go over into potential model one which is exactly what happened right there where this model two accumulation went over into this model one distribution that got confirmed right

(21:57) there and since then we had that massive move down okay so you can see that on this model two we can just Target we can just Target the range low because we also already deviated the low and then we just have to wait for a structure confirmation that will determine if we're either going to go to that low or fulfill this model too and then the moment is model two hit its Target and we got the distribution short that's when we can Target the range low because now there's no reason for it to be model two because you already had

(22:31) one okay it could turn into a model one accumulation that's always possible but we were not expecting it based on the bigger picture another great example is ethereum right here and I've already have it laid out for you so we were trending up uh from the low we were trending up right here our string structure being higher lows and higher highs and right here we created our range okay range high range low and from there we had that deviation one deviating deviation two got our entry trigger right up here okay it was even higher up on the lower

(23:12) time frame um but prior to this model one distribution confirming we already had a sweep of our range low now right here we have our extreme demand and extreme liquidity so we have to be

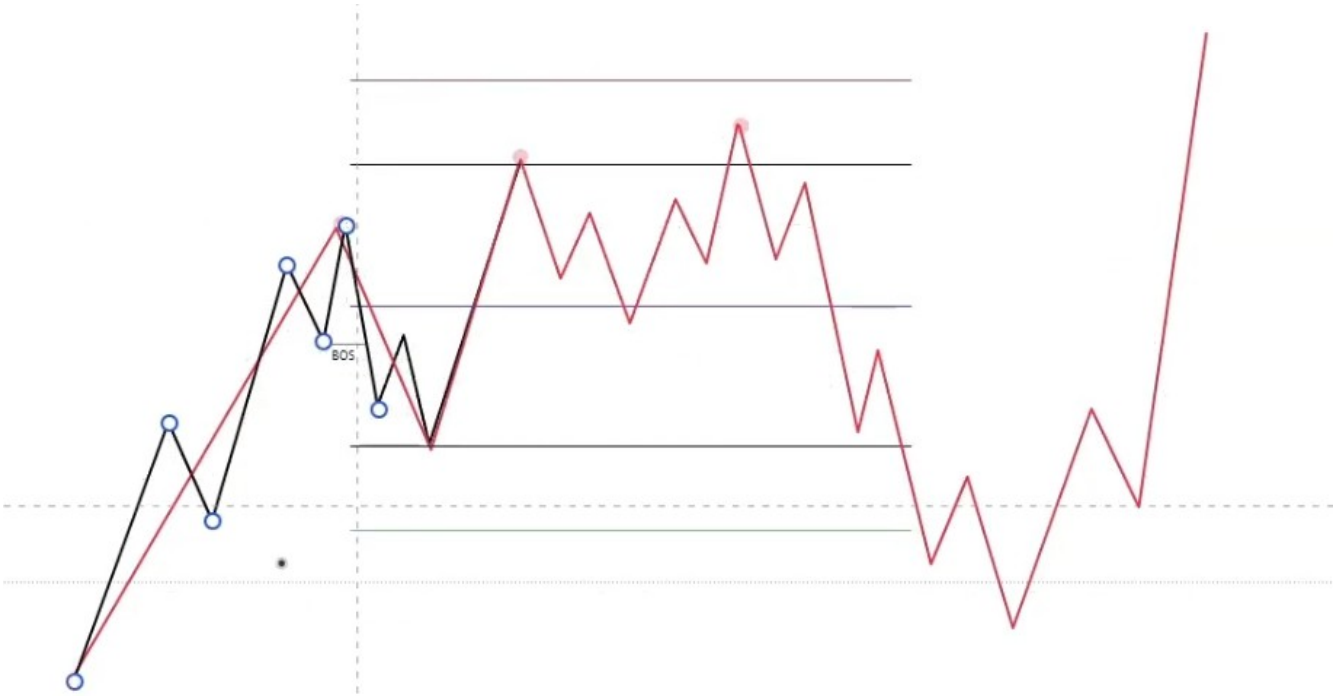
aware that the moment price mitigates that extreme demand or and grabs that extreme liquidity it could turn into a model two so the moment you have a break of structure in here that's your risk on trigger for the long and your risk off trigger for the short and price had a reason to to potentially come higher because we still had that unmitigated

(23:51) Supply Zone above where price um could potentially come back into okay but as you can see we have a picture perfect model one but it doesn't have to hit its Target if we already deviate the low because a distribution like just discussed can turn into a accumulation and when we already deviated the range on both sides prior to confirming one can also flow over into the other so be aware of that okay be aware of that now oh take a sip of my water the second Advanced concept we will be talking about are low time frame

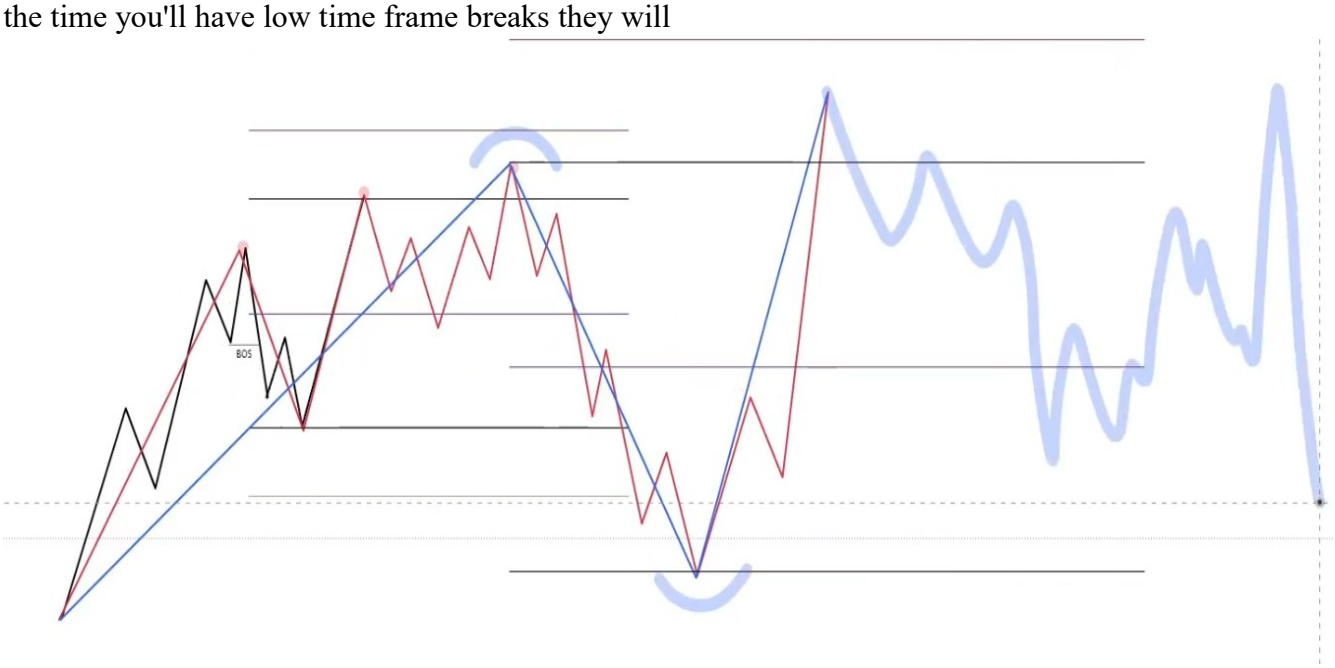
(24:50) ranges turning into high time frame ranges and therefore also low time frame TCT schematic turning into high time frame TCT schematics and it is very important to understand how a low time frame range behaves so it can grow into a higher time frame range because every start of a high time frame range was created on the lower time frame just like your higher Mark Shure pools are created by those pivot pivot Mark Shure breaks on the lower time frame so the higher time frame is important but

the lower time frame makes
(25:39) up the higher time frame and the same goes for ranges okay and understanding um how to properly identify the correct points for the high time frame range you know it will allow you to zoom out reanalyze what price is doing and not get stuck into trading ugly ranges with many wear deviations or being on the wrong side of the market okay so I can already tell you how a low time frame range goes over into a high time frame range okay so just got a notification on my PC just making sure everything is still good but
(26:24) we're all uh good to go okay so what you'll see after an aggressive expansion is Market structure trending up and we know after an aggressive expansion price loves to create a range and that range will always start with a low time frame break on the low time frame you will have some sort of break of structure okay on the low time frame you'll have some sort of break of structure and then it will follow with like maybe maybe one lower high for a lower low and then it will come back up again why will it come back up because

(27:02) your higher time frame structure will look something like this all applying the six candle rule obviously okay so you have those low time frame breaks but those low time frames Bridges make up one Higher time frame Market structure pool and then following that higher time frame our red Market structure drawing in this example this will be your range okay and that will kind of be you know the first range that gets created and and then that range will you know maybe have like a model one maybe it has like a little wof
(27:34) schematic little model one with our one tab our two Tab and our three tab you'll come back inside okay you'll have a rotation down it looks like you're breaking the range low but then you'll come up very aggressively like this okay and why is that well that is because black is representing our low time frame and from our low time frame a mid time frame range started like this with our red mark strcture drawing that broke down but that breakdown is simply a higher low for a higher high on our high time frame the same how our black

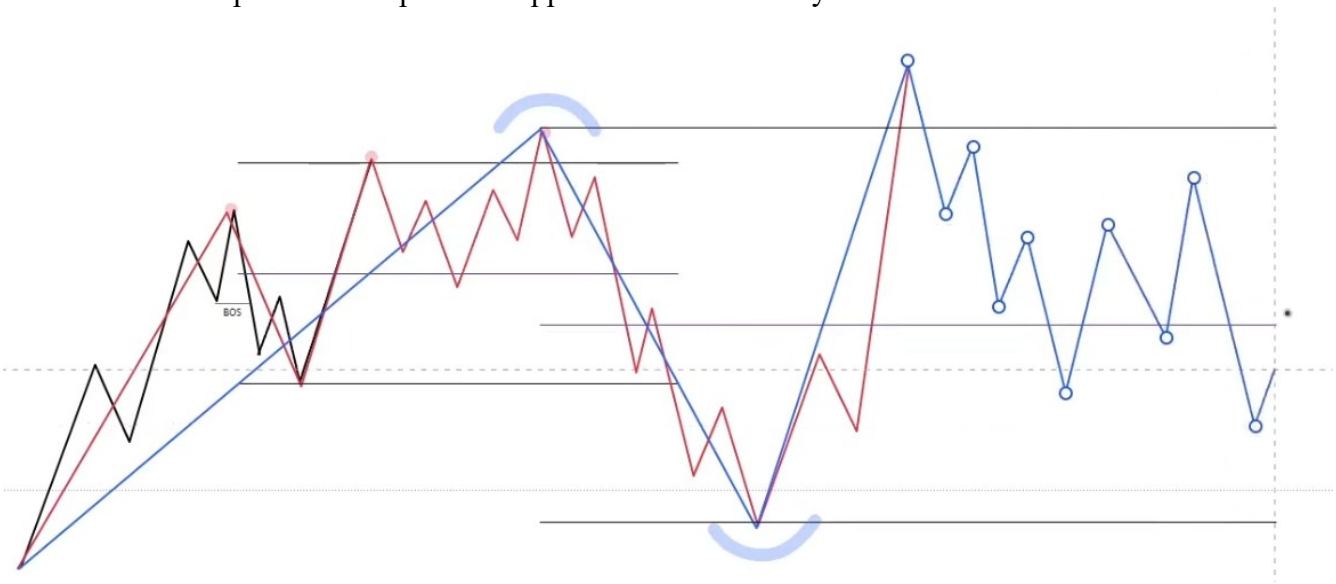


(28:15) market structure break created our red Market structure range our red Market structure range break created our blue Market structure range okay where this will be your Range High right here this will be your Range High and then this will be your range low and now we have a macro range okay that can have many rotations before you know potentially starting a TCT schematic but this is exactly okay this is exactly how a low time frame range goes over into a high time frame range it happens all the time you'll have low time frame breaks they will



(28:56) make up for a higher time frame Market structure that will have its own little range those that range will start deviating towards the upside and downside probably both and create in that way a bigger range where our black market structure is representing our low time frame red right now our mid-time frame blue our high time frame okay and then blue can come back inside and continue forming a range and do whatever it wants to do okay and I'm not just making this up because right next

to us we have the perfect example this happens all the time okay



(29:39) and many people will get stuck into potentially you know trying to keep on trading this red range okay and they will just count this as a deviation because maybe technically speaking it is valid but they have to realize that rationality also goes along with away and this just looks way cleaner and that's why we always have to zoom out okay it's very important to zoom out before zooming in again and to not get stuck on the lower time frame so let's look at it from a real life trading example okay so I'm on the 15 minute

(30:18) right now I'm on the 15 minute and we can see that we are trending up and we have a high and we have a higher low higher high higher low higher high let's make this that black mark strcture drawing and hey we can kind of see a range here we're trending up poor range from top to bottom use our DL to use our DL to kind of have a sketchy close above it is also on the 45 very very very sketchy which still counted as a deviation extended extended down towards a deviation low and we can see we kind of had a local distribution here a one a

(31:10) two and a three uh that hit its Target okay and got that rotation back down so we had a local distribution right here a one two and a three that broke down from the range obviously closing below our dl2 like this is an obvious break compared to that local close above we got right there now what happened is instead if we follow this structure that obviously broke back the bearish right here instead of having a lower high for a lower low what we had was a move back up why did this happen well one we had Supply up there so there was a reason to

(31:58) but but if I zoom out if I zoom out our black mark structure drawing on the 15 disappears on the two and if I draw my two-hour structure we have a higher low and we have a higher high okay let's make that red see how that's literally representing what I just drew for you guys so we had that local yov right here that broke back the bearish but instead of having a lower high for a lower low we created just another Market structure pool so we can ignore that black mark strcture drawing now and then draw our range from top to

(32:37) bottom range high range low and then here we are on a mid time frame range and you can see how what we just traded completely disappeared okay from there we deviated our high this extended and we deviated once more right right there indicating yet again a model one distribution okay broke down did not have a proper close above it because it came into this uh goodlook structure Demand right here indicating a deviation and we got a full rotation back up okay full rotation back up towards our Range High just like this

(33:29) now this is why it is so important to zoom out okay because if you're not zooming out you will just continue using this as your range starting point count this as a deviation extend your range like this and you would have never caught the good trades we just discussed um on the S SMP where this was a model one because you have one tab two tab three tab four tab five five Tab and you will not know what you are seeing on the chart basically because you're like I have five tabs but TCT schematics are three no if I now zoom out on the sixh hour

(34:10) time frame this structure pool disappears and if I have to draw uh structure using the six candle where we have a higher low and a higher high and then we have a higher low and then we have a higher High completely ignoring this model one distribution that we had on the mid time frame and now this is representing our high time frame okay so that first beginning range that was its own little thing that was already its own little yov that hit its Target and now we are ready to start a new Range using our six hour time

(34:50) frame from there we have a Range High deviation one range low uh or range low deviation one and then we extend it and now we got that model one so you could have only gotten and traded that model one as a model one if you understood to always check um the higher time frames and understand how those low time frame ranges that started here turned into a mid time frame range here turned into a high time frame range here and it's always the same story where you have that low time frame break that then breaks still back to bullish

(35:29) right here because it was a higher time frame Market strcture pool and the same for mid-time frame to high time frame so understanding I need more water but understanding how to redraw your new Range points will obviously allow you to look at the right TCT schematic again but that is not just it because on every TCT schematic we traded in lecture 5B I taught you guys one thing to look out for if you're not remembering it shame on you right now on every TCT schematic we traded in lecture 5B I told you guys to look out for one

(36:21) thing always and that is to make sure what the highest time frame is that your range is valid on and now let me explain okay let me explain so I told you guys check what the highest time frame is that your range is valid on and why is that well that is because okay that is because you could have different or basically the same TCT schematics within one range depending on the low time frame and the high time frame in that range so let's look at at an example on ethereum right here price is obviously

trending up right price is obviously
(37:21) trending up and we have a high and we have a higher low and we have a higher high okay in uptrend we pull range from top to bottom we have our dl2 we can clearly see this perfectly rejected from our DL tool line not closing above it indicating a deviation okay and then we have our range low now if I zoom in guys on the 15 minute you know the five to 15 you can clearly see it you can clearly see it that okay we deviate our high so let's extend it I having trouble getting that perfectly there you go let's extend it
(38:13) and then let's zoom in and we can see right here we have this two-minute Supply kind of creating a little supply chain right here this was basically a structure Supply this ire move up kind of pulling it up to that inefficiency right here because this is the only Supply remaining that's when I'll pull it up to still use that mitigated one and we have something like this now if I'm if I'm on the five minute time frame guys this looks pretty clean right this looks pretty clean where we will have a One Tap two tap three tap okay what

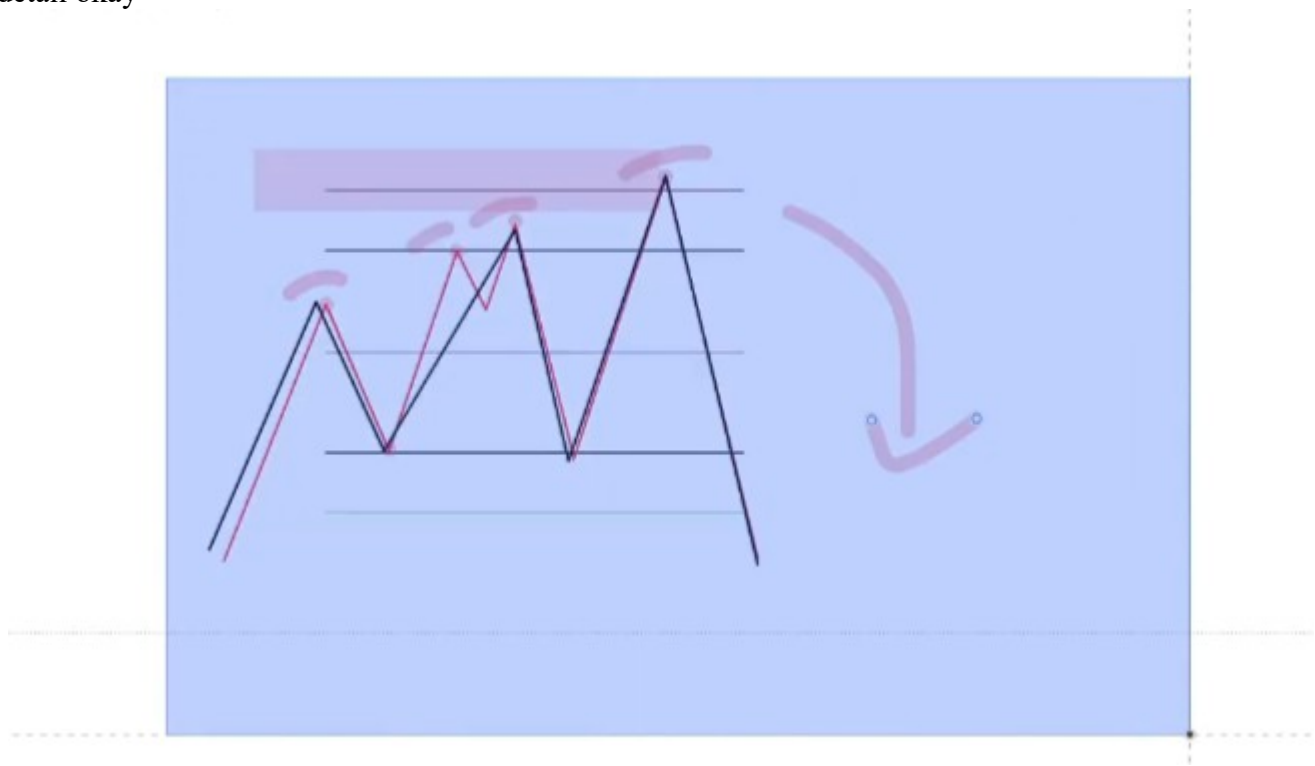
(39:03) happens price comes back down all the way towards the range low hitting its Target absolute lovely trade but we already traded A1 A2 and A3 model 2 TCT distribution confirming it right here on that break okay however I need to check what is the highest time frame that my range is valid on why well if I zoom out on the 1 hour this is a valid range because you can draw using the six candle rule two candles down two candles up right here so this is a 1 hour range but what happens on the 1 hour my second Tab and my third tab completely
(39:55) disappear because this is not a valid schematic on the 1 hour because I can draw this using the six candle rule where each uh Pivot Point has those two candles so this is not a valid model two on the 1 hour but the range is valid on the 1 hour so what I have to identify is hey right now my extreme Supply is this 45 minute order block right here if I zoom out out on the 1 hour and price comes back in here that will be and that could be my new third tap so you can kind of trade a model two twice okay you can trade it
(40:51) twice like this you can trade it twice one time on the 5 to 10 minute that already hit its Target and then we came back for A1 A1 A2 and A3 but the only way you would have traded this as a model 2 distribution is if you would have understand that you always need to check what the highest time frame that your range is valid on and then understand the fact that you can trade a more local model two and then also a higher model two higher time frame model two okay but only if you knew the information I just taught you guys you could have catched

(41:48) that short and that ended up being an absolute The Banger of a trade so always when you're tap to and your tab three are way more narrow and close by than your tab one and your tab two right so your tab two and your tab three are way closer than your tab one and your tab two that's when you have to be aware that hey if I zoom out this will probably look like one deviation okay if I zoom out this is just one move up and one move down and this is our third tap okay where the three moves to here and it can also happen when we're trading a model one

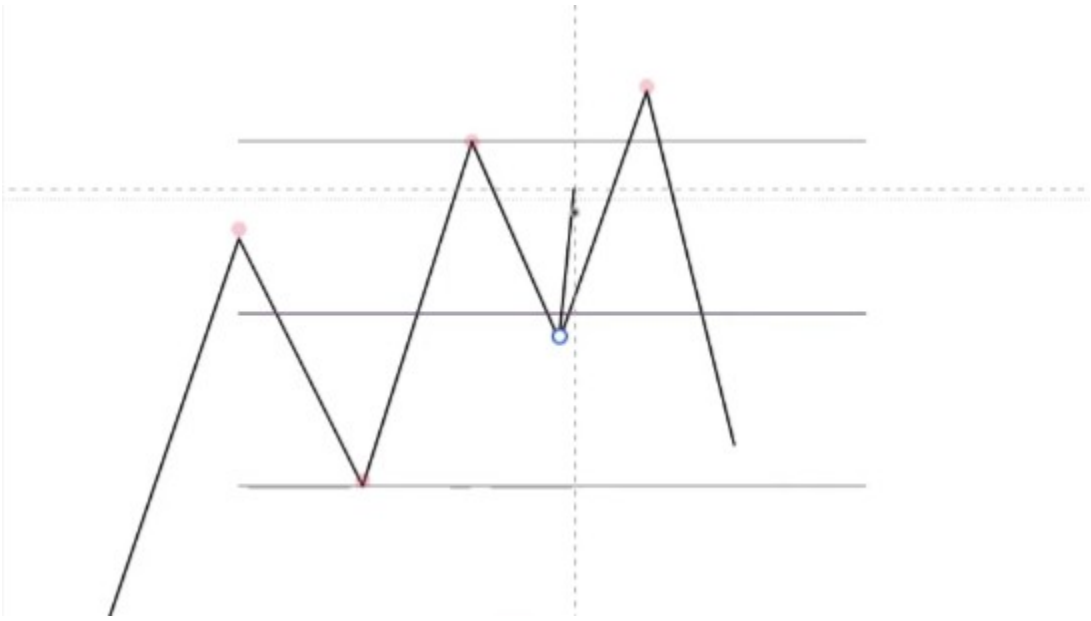
(42:30) okay so let's say this is representing our 5 minute time frame okay this is representing our five minute time frame where we have our Range High our range low deviation one let's extend it up deviation to okay but then what happens is this and then if you stay on this time frame this will look like four tabs but maybe on the 30 minute if this is representing your five on the 30 it will look like this okay it will look like this where your tab two and your tab three on the five just look like one deviation on the 30 and this is often

(43:31) the time where you have like Supply up here remaining that needs to be mitigated okay until we can actually start moving down and you'll have this you know this mid time frame overruling that low time frame but you can trade the low time frame schematic okay you can trade the low time frame schematic just be aware that it could come back up to create that higher time frame schematic and you need to be aware of it most of the time when your tab two and your tab three are way close closer than your tab one and your tab two okay it's

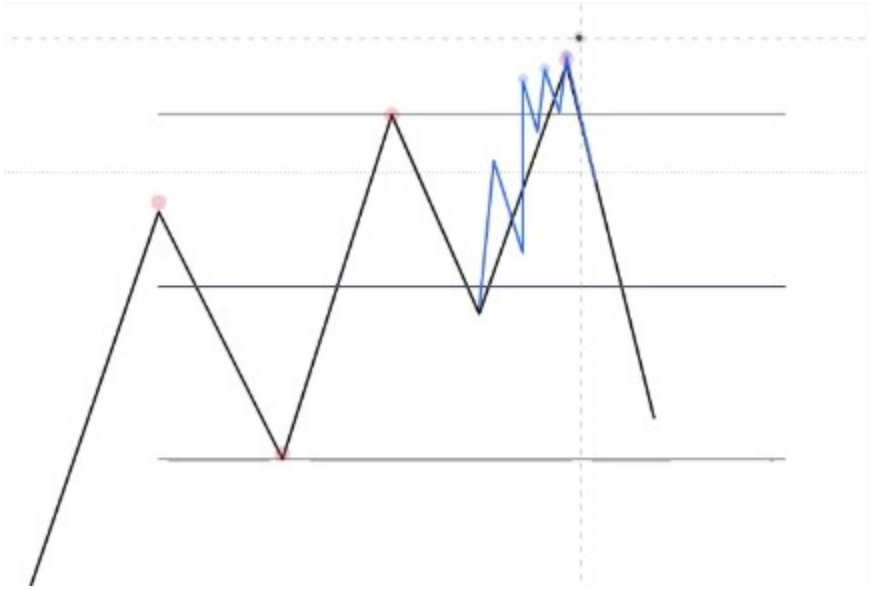
(44:01) my screen is a bit laggy so my apologies for that but um that is basically the low time frame ranges turning into high time frame ranges and then also low time frame schematics turning into high time frame schematics so if you see a four tap a one a two a three a four and it has that aggressive move towards the downside recheck it again now knowing this information it will probably just be a three tab on a higher time frame so let's delete all of this let's delete all of this and let's talk about our next big detail okay



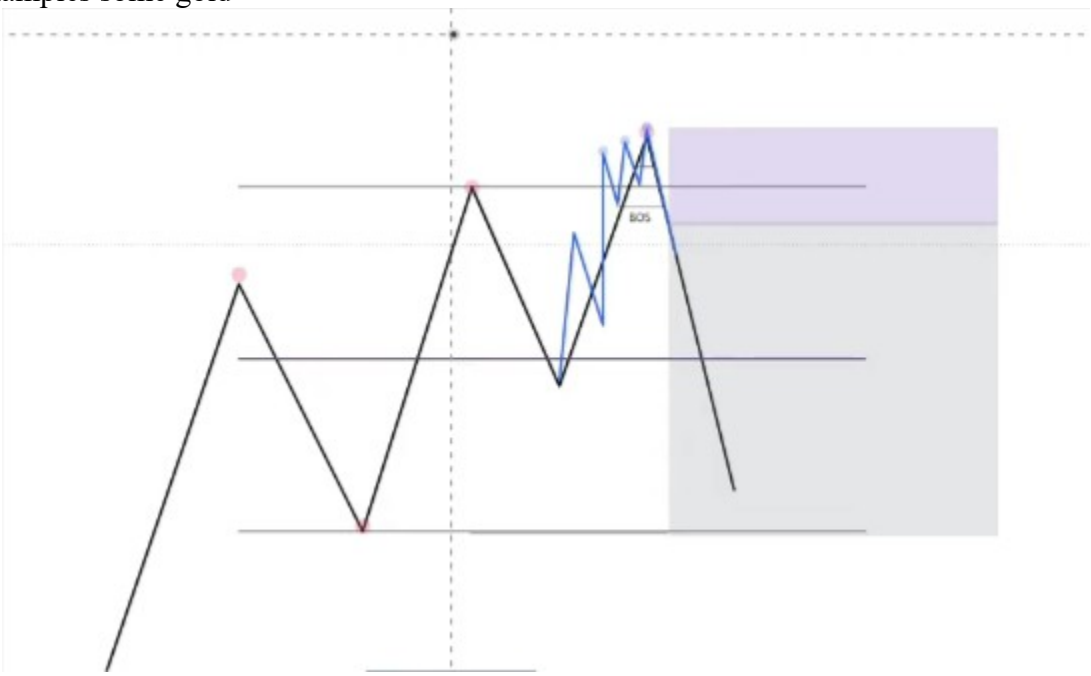
(44:55) so checking if everything is good going okay yes it's all going perfectly fine that's good good good good back to action okay in the third Advanced concept we will be talking about wov in wov and how this can drastically improve our risk to reward when trading TCT schematics while also giving us extra confidence in our setups so what I mean when I'm talking about yov and yov is that our third tap okay our third tap of our initial TCT schematic has its own little TCT schematic this way we can have an entry confirmation way earlier than the
(45:52) original break of structure level causing our risk to reward to improve d drastically so what do I mean well let's say we have a model one distribution okay just like this model one distribution where we have our range high range low deviation one deviation 2 there you go now what could be the case what could be the case is that on the way or and on this move up towards that third tap High we have lower time frame structure okay that's completely normal but that lower time frame structure could also have his little



(46:42) range that could be a white cof let's make it blue let's put the tops in there tab one tab two tab three so our own blue Marcos structure pool could have its own little range where the bigger third tab will be one of the tabs of that own local little TCT schematic and this way let's say our main Market structure low to break was you know right here which in this scenario will be obviously really good now we can already enter all the way around up here because that will be your local confirmation for the blue TCT model one schematic right



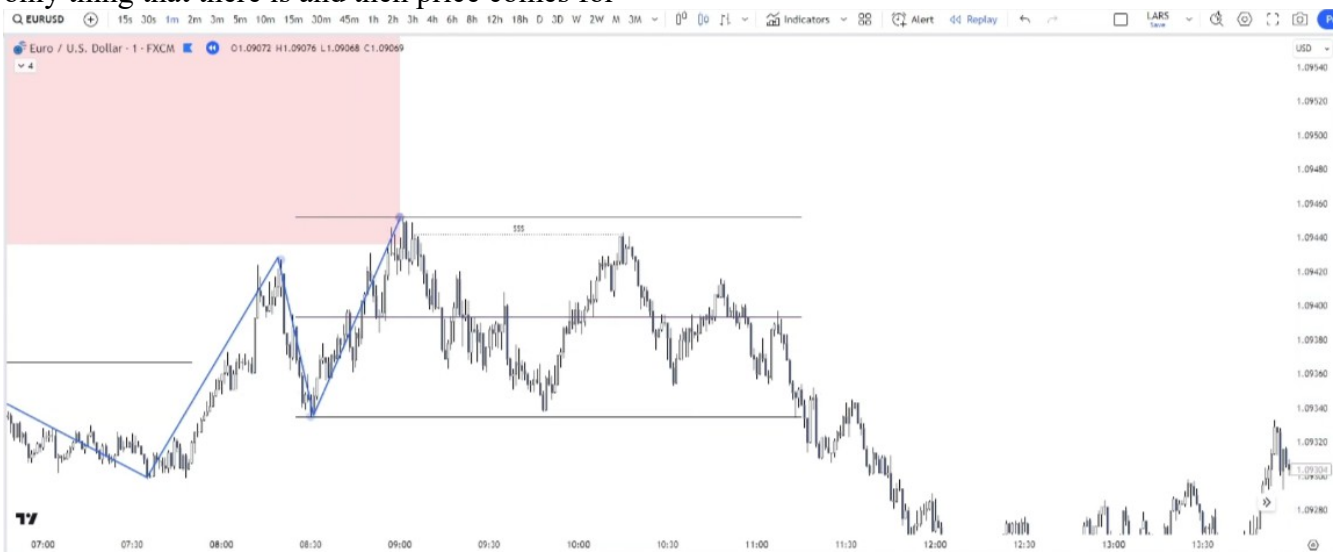
(47:38) so we can enter here Target all the way down instead of waiting to have to enter all the way down here to Target that low which will cause a massive increase in our risk to reward but I want you guys to understand when I'm talking about yov and yov I mean a yov in my third a a a local TCT schematic in my third tap of the bigger TCT schematic okay so putting it to practice showing it in a real trading environment we can see uh Euro USD on Forex I like to switch it up you know show some crypto examples some gold



(48:15) examples some S&P some you know some uh uh Forex so what we can see right here is we have our range low let's make this back to 20 not 2012 where have our range low we have our Range High we have our deviation one we have our deviation 2 coming into Supply indicating a model one distribution if I just had to wait for normal structure Let's uh let's do five minute structure okay if I have to confirm my entry using five minute structure you will see we have high low higher low higher high right here this will be your Market

(48:57) low this will be your break of structure level to wait for so you can enter on the break right here put your stop loss above the high Target the low okay and you would have had an amazing trade with a risk to reward of 2.2 okay that was your risk reward 2.2 now as you can see right here okay if I put this to the right so the level and the horizontal level doesn't go through our local range as we can see right here we have an uptrend in our blue Mark strcture drawing okay so when we're trending up we pull our range from top

(49:35) to bottom and we can see we have a local Range High local range low deviation one let's extend it and right here we grab probably extreme liquidity on the lower time frame okay let's go into one minute right here we grabbed for sure extreme liquidity we're trading a lower time frame um trading a lower time frame schematic right here so yeah you can just kind of use this area as your extreme liquidity and extreme Supply it got mitigated right there let's pull it above because literally the only thing that there is and then price comes for



(50:20) it okay third Tab and right here we broke Market structure so right there on that breaker structure that already confirms right on this candle right here that already confirms this uh local model 2 distribution schematic but we know if we lose that range low of this local range we can have a confirm a confirmed macro TCT uh model one distribution schematic so we can already enter here just like we can enter on lower time frame structure and then wait for our higher time frame to break as well well obviously the moment we were at that low

(51:04) we broke and now we have the same Target guys we have the exact same Target of the same setup but where we had that 2.2 RTO reward now now we have nine now we have nine guys which is an absolute Banger of a trade it's absolutely insane okay just by trading the local distribution inside of the bigger distribution we can improve our risk reward and add an extra 7% net gain on the account okay which is absolutely amazing now another great example was the public short the public short I took on ethereum and this was absolutely a

(51:54) beauty of a short okay so what we can see right here on ethereum is around a 12-hour range we went up we went down higher low for the higher high there we go pull our range from top to bottom have our Range High have our range low right here and then we got that deviation one deviation one deviation two indicating a model one distribution okay now if we go on the lower time frame to see where that structure kind of is I can see on the 2hour here pulling my structure from bottom to top you have a high higher low higher high

(52:37) higher low higher high so right here was our Market structure low we initially SFP it and then we kind of kept SFP it over and over again until until right here that's when we got a very convincing break okay because then you kind of ladder it down because we get those expansions away from it so if I had to you know confirm this model one distribution it would it will not be until here putting that stop loss all the way above there just to Target the low and you would have around a you know a 1.46 risk to reward which is decent but

(53:15) not the best okay now if something may have already caught your attention this was the range we just used to you know talk about low time frame and high time frame frame uh TCT schematics I don't know why my trading view is uh giving up on me right now but okay I think we're all good to go okay so if May something may have already caught your attention it is that this right here obviously has its own little range and is that range we just talked about right it's that range we just talked about where it had had

(53:57) that it had two model two schematics okay two model two schematics where right here we had our range Range High deviation one deviation two or or or third tap I mean let's make those blue and then we could have confirmed our entry right there let's zoom in on a lower time frame like the one

there we go let's see where we can get that structure confirmation there you go right here on the 2 minute 2 to 1 minute we get that structure confirmation price comes back for a lower high in our structure Supply let's say we entered uh on that

(55:03) retest put our stop loss above our third tap high now we can already enter up there for the Target all the way down to here boom that way okay that way our risk to reward changes from that 1.5 we were just talking about all the way to a 13 risor reward and you you guys can see the move down was very smooth so we had a one we had a two we had a three but our third tab had its own little one two three y COV in yov okay absolutely key absolutely effective last example want to get into is on um the S&P range we were just

(55:55) talking about so as you can see we had that one we had that two we had that three we were already expecting a rejection right here because you know we were in this macro range on [Music] um on the S&P 500 and then we came into that extreme Supply Zone which is nice resistance okay came into extreme Supply Zone and we were kind of expecting a range rotation down ignore the ugly candles on aanda they're having some problems with their data um but if we check how we came up there into that third tap High we have a high higher low

(56:31) higher high clearly indicating a range by already how extended and um wide this V is and then we have this okay so we can see right here we have our Range High we have our range low and and we have our deviation one okay so zooming in we can see that we have a 15minute order block right here which is our extreme Supply which got tapped right there so the moment this got tapped and this liquidity got grabbed we were um meeting the requirements of a third tap indicating a potential mude distribution and then we just have to

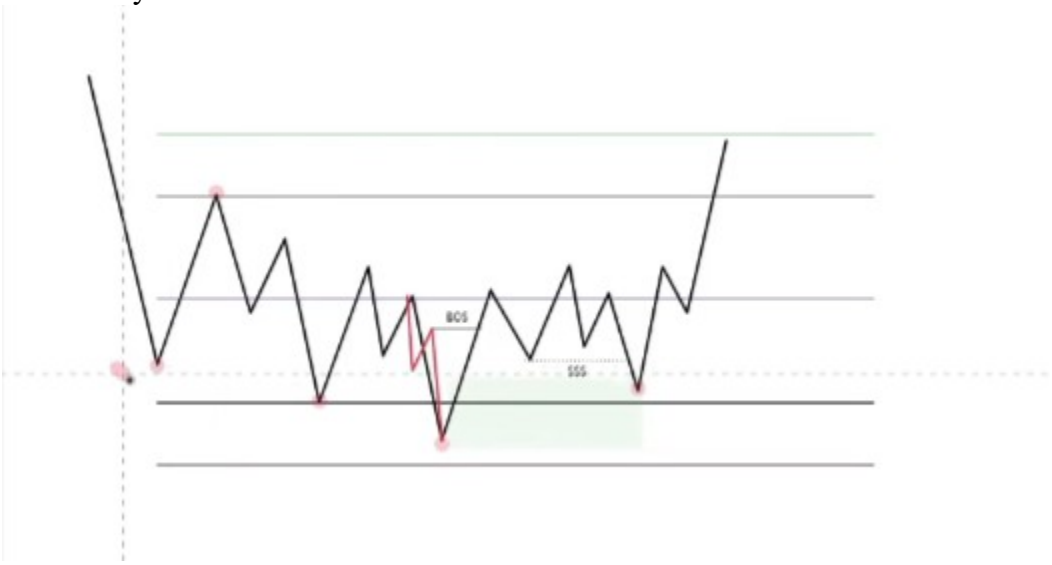
(57:22) zoom in on the lower time frame hopefully AA actually had a conf information I don't trade on the one that guys I just pulled it up for the thing very ugly candles ignore it but this is just a higher lows and higher highs okay higher lows and higher highs right here we had that break of structure and that is where you could have confirmed your entry on the break put your stop loss above the high and then Target all the way down towards the range low for a 21 risk reward that will be a 21 risk to reward um versus

(58:11) a two risk reward if you entered on the break of that range low or that Mark low uh which you would have to wait for if you didn't know about uh TCT schematics inside of TCT schematics and wov and wov okay you see that a two R reward versus a 21 absolutely absolutely crazy so the last Advanced concept I want to discuss with you guys is model ones flowing over into model 2os so let's say price is trending down right here and we form our range and and then we have a model one TCT accumulation schematic okay where we have our range Low Range High

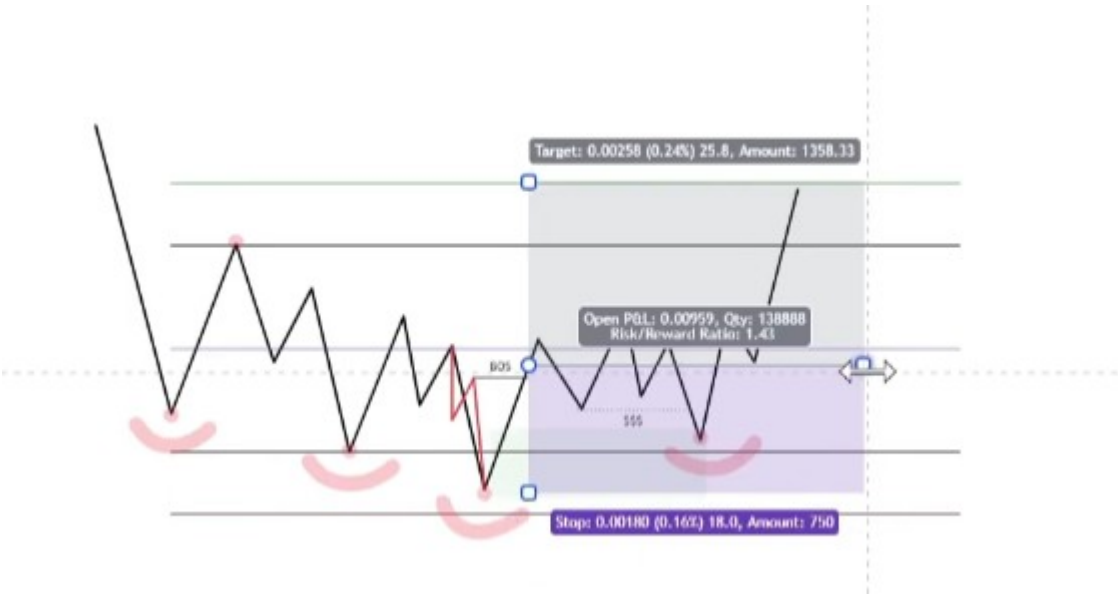
(59:09) deviation one let's extend our new Range low to the deviation low let's make this black so it's more visible and then we got that deviation too okay coming back inside right here we broke structure back to bullish on the lower time frame confirming the TCT model one accumulation schematic now what could happen What could happen is that price follows up with a higher low for a higher high and then maybe comes back down sweeping that liquidity before moving higher okay well right here it must have then swept extreme liquidity and or H it hit some

(59:54) Fort of extreme demand confirming this as a valid third tab if we were to look at it from a model 2 perspective okay so you kind of have that one you kind of have that one that two that three but prior to price uh tapping your Range High hitting its Target it comes back down and it creates kind of a fourth tab which is a higher low confirming that this could also be a one two and three like this okay so it's kind of a model one that flows over into a model two and this happens quite often okay and what

we can do uh and why this



(1:00:42) is so important to know and to understand is one we can improve our risk to reward just like within the yov within yov schematics right here if I entered long okay on the break of structure and I put my stop loss below my third tabl low and I would Target the high I would have around a onetoone risk reward it's not the best but it's an example okay well what happens if price starts putting in that fourth tap indicating this model one flowing over into a model two and we get a long confirmation right down here



(1:01:26) on that uh red Market structure break that means that this is our new yof Point okay because this is the third tab from a model 2 perspective meaning the invalidation will always be below your yof point and since this has become our new yof Point okay we can Trill our stop loss down towards that new low now right here here I'm R risking 1% on a 0.

(1:02:05) 17 stop loss now I'm moving it down to 0.1 so if I was risking 100 now I'm only risking around 60 so what you can do is you can add that $40 risk that's gone because you trilled your stop-loss you can add it back on the trade right here you can add that risk back improving your risk TR reward from only um from only a around a one to a around A2 okay because you'll have an average entry that's right around there your stop loss will be below that low and now you just doubled your risk

to reward by trailing your stop loss to your new wof point if it meets the requirement of a

(1:02:49) third tap of the TCT schematics and then you add that risk back on the break of structure conf confirming the model two okay so this happens all the time and sometimes you'll even see that tab two and tab three they disappear okay because they're too close and it will just be a bigger one bigger two bigger three okay so it's it's important that you know this otherwise one you can maybe start stressing when you see price coming back down below your entry um but if you see this extreme liquidity point and you see obvious looking demand you

(1:03:29) you already know in your mind that hey this could potentially turn into a bigger uh accumulation schematic and if it does guys if it does usually schematics where the model one flows over into a model two they have follow through towards the upside why well it it it just shows that the market maker is not leaving any sell side liquidity behind and not leing leaving any demand behind meaning he's fully positioning himself we already had um the model one where he grabbed sells side liquidity twice on the two deviations but he even made price come

(1:04:09) back for our extreme liquidity Point within the range meaning his really positioning himself to push price higher so normally when we have a good-look model one flowing over into model two it tends to have follow through Beyond it range extreme point so a good example right here on euro is that price was trending down coming into demand okay so we had lower highs and lower lows coming into Demand right here in the downtrend we pull our range from bottom to top and then we can see right here we can see that first deviation staying inside of

(1:04:44) our dl2 so nothing to worry about from a break perspective price came back inside let's extend our range low towards our new deviation low and right here we got our deviation to indicating a potential model one uh accumulation schematic now we have to confirm the schematic so let's go on a lower time frame and we can see right here on the lower time frame we have lower highs and lower lows okay and right here we have that break back inside the original range values and we can go long right there okay so right here we can go long on

(1:05:26) this break of structure we put our stop loss below our yov low which is the invalidation and then we target our Range High for a lovely three risk to reward that's amazing risk one make 3.6 okay now if I were to check okay where is my extreme demand and where is my extreme liquidity your extreme liquidity is right below that low that's the most obvious Mark Shure low uh prior to taking your um third tab low and obvious demand there's not that much obvious demand so I would use this pullback area that got that got mitigated ever so slightly here

(1:06:11) because it's the only demand area remaining I'll pull it below that demand mitigation like set in the demand tutorial or lecture and then that will be my valid potential third tap okay so as we can see we confirmed the model One price went up but we were curving over coming back down now instead of stressing we should realize hey it can either mitigate this extreme demand zone or grab extreme liquidity to go over into a model two this or accumulation where this model one is flowing over into the model two now right here we mitigate

(1:06:45) that extreme demand and we break structure back to bullish okay confirming our accumulation schematic now what does that mean for our trade that's already open it means that right now okay our entry is right here and our stop loss is right there but the moment we get the breakout structure right here the new invalidation of the trade becomes below this low because that's your new yof Point your new yov low okay so what you can do is you can Trill your stop loss okay you can Trill your stop loss below that low AKA that low is
(1:07:33) above your entry meaning your stop- loss can go to entry and you are der risked not risking any more money on the trade and what you can do is you can just add back the 1% risk right there and long it back up so instead of only having this position open which will net you around three RR you can put your stop loss to entry on this position open a new position with a 1% risk below that low because you want to risk 1% on the setup and now instead of making three you're making three plus two so you're making five and I told you

(1:08:11) that if a yov schematic model one flows over into model two especially on the mid time frame you can expect some follow through and look what happened look what happened price got the follow through so maybe instead of just targeting the high we would Target this liquidity curve right up here you know fill some inefficiency right there and have this uh extreme or this good-looking Supply zone so maybe you can even extend beyond the Range High and just you know talk about hey maybe

you want to grab all that liquidity

(1:08:41) curve or all the liquidity from the curve right here and fill this in efficiency tapping into that uh structure Supply Zone and then you can even extend your targets all the way up there and you're netting over 6% and 5% making 11% in one trade idea okay guys you really want to benefit when you have such a clean looking schematic and you want to really want to benefit when you are right when you know it's a good setup look how you can app more always look how to app more when winning okay if I zoom out now on let's

(1:09:17) say the 3 hour and we can check this range you can see on the three hour that this is also a valid range but your tab two and your tab three disappear right your top two and your top three disappear right there and this is just a one this is just a two this is just a three right so on the three hour it's a model two and then on the lower time frame it's a model one flowing over into model two so that's something that happens quite often quite often and uh it's just good to know how you can you know add more risk to the setup because

(1:09:50) it just shows more Market maker involvement and it's really not leaving any demand or liquidity onr and unmitigated okay now lastly guys before we will wrap it up is I want to talk about that TCT schematics are absolutely everywhere okay they are absolutely everywhere and especially in high time frame pivot Points okay why well a pivot point indicates a strong move away from a certain price

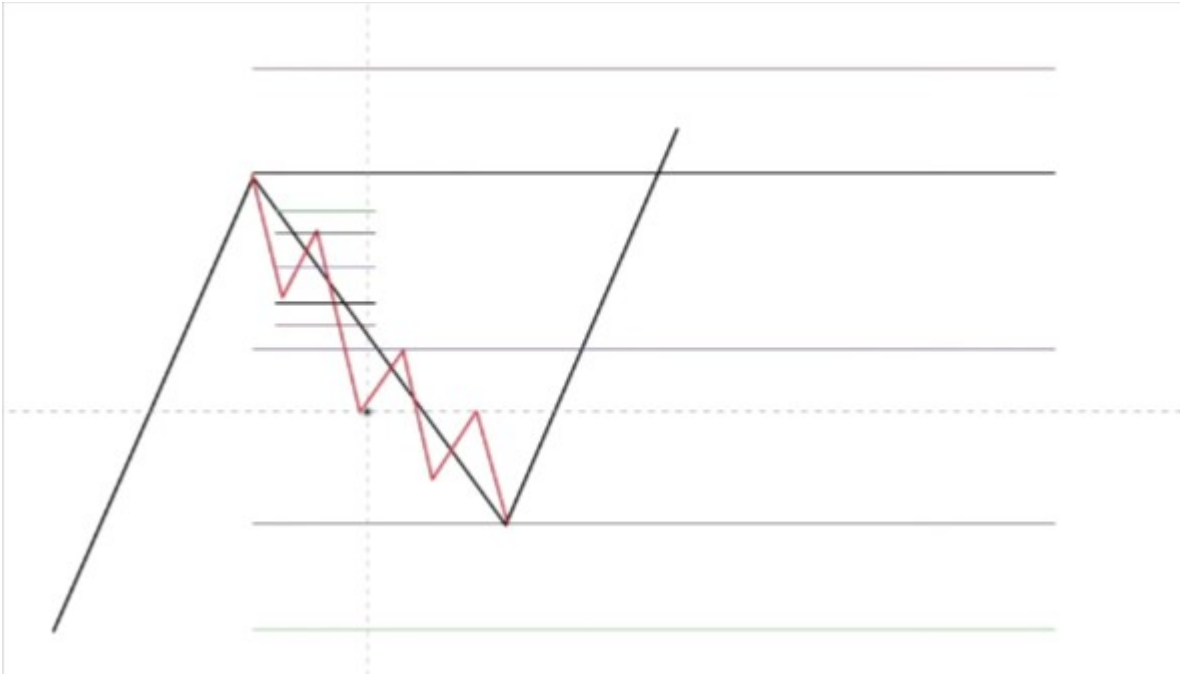
point and price is only going to have a strong move away if Market maker stepped in and moved price strongly away so in almost every major pivot

(1:10:39) point it doesn't have to be in the exact low or in the exact high but around it you will find TCT schematics so I've laid out the high time frame SL mid time frame TCT schematics on B BTC and this is the one we discussed where the dist ution went over into the accumulation but right here we can see in that in and SL around that pivot point we had an amazing entry netting you over around 10% coming to that high right here in that Pivot Point you had a distribution within a distribution netting you over 16% targeting that low and then within

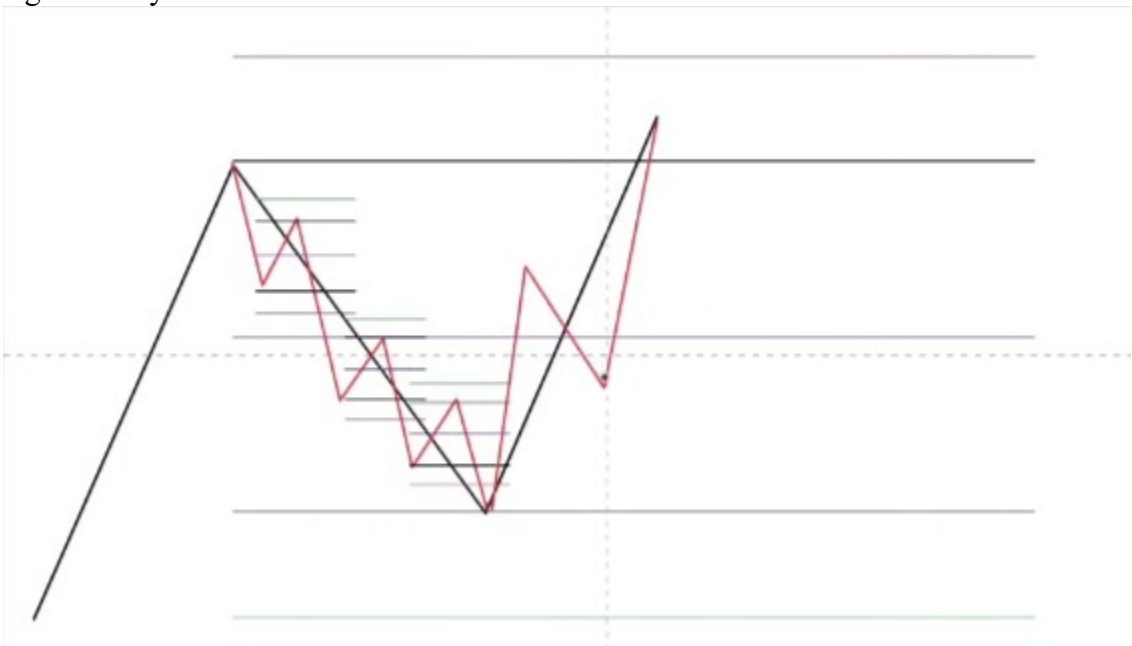
(1:11:15) that distribution you had two accum you had an accumulation and another distribution netting you over five and six% right here prior to dumping more down you had a distribution right here before pumping up you had an accumulation this was the most recent one that we absolutely nailed on X absolutely nailed this one KN you over 11% and right here in that bottom you again had a model one TCT accumulation schematic and I'm just showing you guys I'm just showing you the higher to Mid time frame pivot Points if I zoom in on

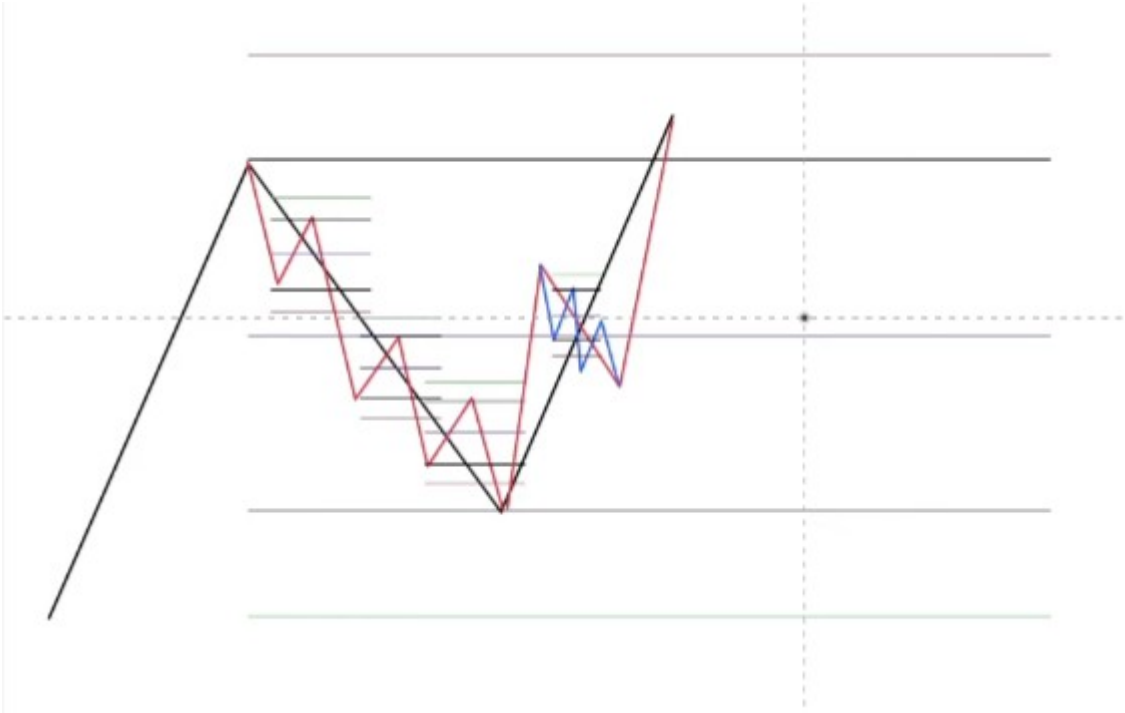
(1:11:49) the 3 minutes and the five minutes we will find TCT schematics all over the place I'm already seeing one right here right there I can already see that you have a range high range low deviation one lower high nice liquidity trail move down to follow hitting its Target right so they're absolutely everywhere absolutely everywhere and in the next lecture we will be talking I think about risk management and the power of only making 1% and how to use leverage to our advantage what leverage actually is and you will realize that you don't need

(1:12:24) that many trades to become very very very profitable and with TCT schematics the possibilities are literally endless okay they're endless because I taught you guys overlapping structure so if price is trending up okay that means on a higher time frame for example if price is trending up that means that we could have a potential range right here from top to bottom that could turn into a TCT schematic however to get from point A to point B we need to have some sort of downward structure right and in that downward structure every downpour could



(1:13:01) be a potential range and that could be a potential range and that could be a potential range and then even dissecting that red mark suure drawing in lower time frame structure like our blue Mark strcture drawing to get you know from that point to that point that point to that point we need more structure so you know using that overlapping structure structure of that shows you how many range possibilities there also are and every range possibility is a TCT schematic possibility if requirements are met right so they're





(1:13:39) absolutely everywhere and you just need to pick out the one and we together are going to pick out the one that will be the highest probability to ensure your profitability in this trading game okay guys so that was it for the advanced TT TCT lecture I'll see all of you guys in lecture s peace out
